

How Does Routing Work in my App?

- Routing and Client-side Routing

Routing in web applications is a mechanism where HTTP requests are routed to the code that handles them. It determines what should happen when a user visits a page. Client-side Routing in React renders the appropriate information on the DOM using its component structure.

- REST

REST is an architectural style for an application program interface. It organizes an application in different modules. A REST API uses commands to obtain resources and uses HTTP methodologies to represent it.

Example:

GET / apples

POST /apples

PATCH /apples

DELETE /apple
